

COMPSYS™ - DYNAMIC SIMULATION SERVICE

OPTIMISATION OF HOT BY PASS VALVE C_v

Hot by pass line

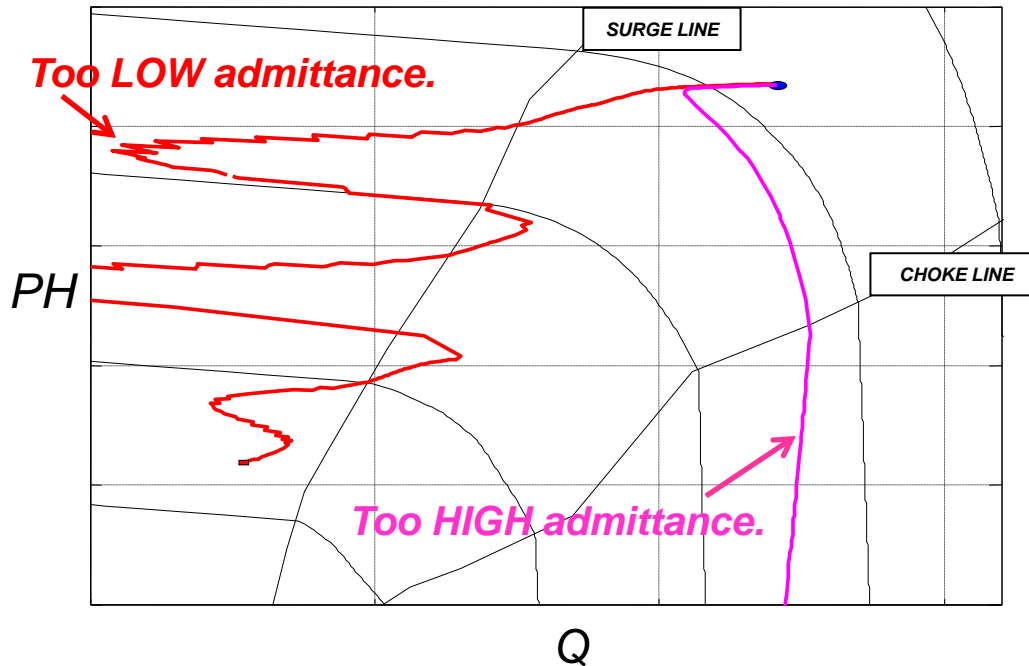

The hot by pass line provides an important **surge protection system** during the shut down of gas compression station.

Trip event

Traditional sizing

The sizing is generally based on the maximum mass flow rate provided by the compressor during normal operating conditions.

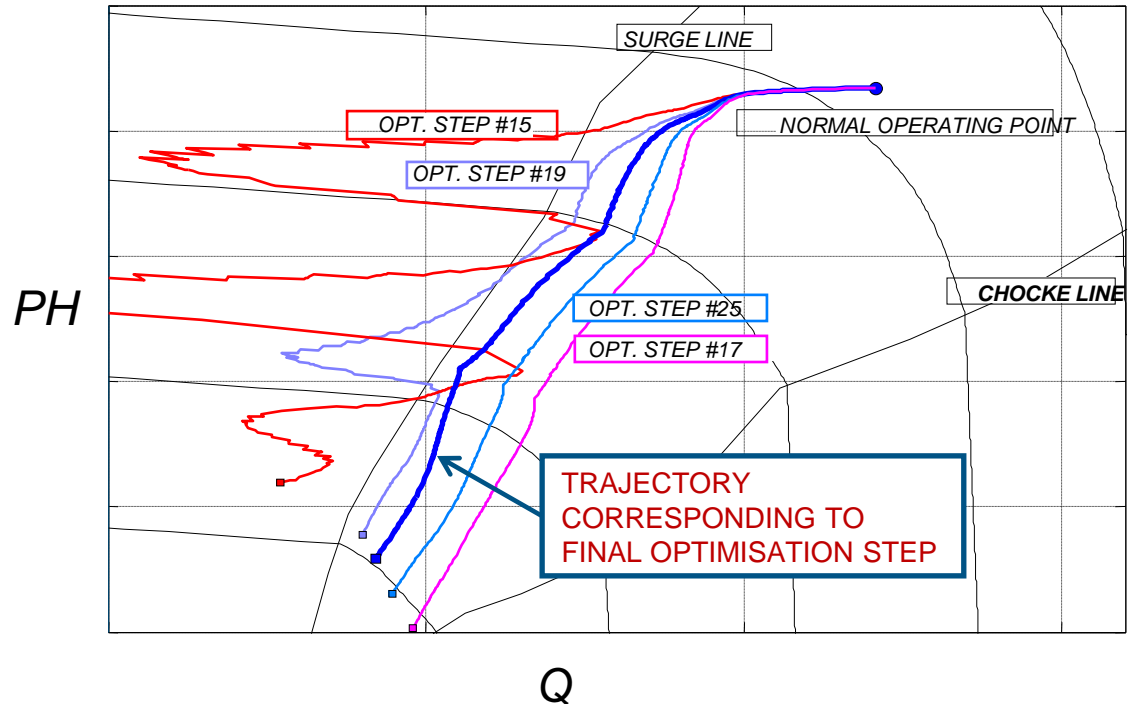

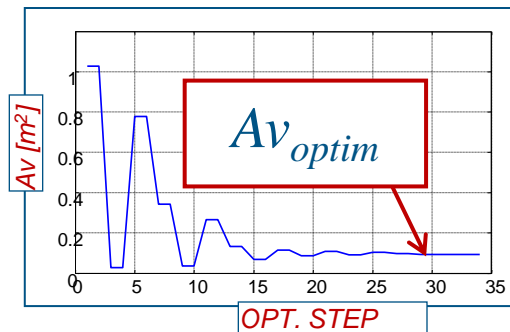

Limits of this approach:

- “static” calculation
- non optimised line admittance
- Neglecting plant dynamic interaction

SATE sizing procedure

Features:

- **optimization** procedure based on **BFGS algorithm**
- considers plant *dynamics*
- applied to the deviation of the simulated **operating point trajectory** from the surge line

Iterative optimization procedure:
Optimum admittance corresponds to the **minimum deviation** of the compressor trajectory from the surge line
→ **ideal valve size**
